CHAPTER 4

LECTURE OUTLINE

I. INTRODUCTION
   A. A tissue is a group of similar cells that usually have a similar embryological origin and are specialized for a particular function.
      1. The nature of the extracellular material that surrounds the connections between the cells that compose the tissue influence the structure and properties of a specific tissue.
      2. The science that deals with the study of tissues is called histology.
   B. Pathologists, physicians who specialize in laboratory studies of cells and tissues, aid other physicians in making diagnoses; they also perform autopsies. Analysis of biopsies, samples of living tissue removed for microscopic examination, is a chief responsibility of a pathologist.

II. TYPES OF TISSUES AND THEIR ORIGINS
   A. Depending on their function and structure, the various tissues of the body are classified into four principal types.
      1. Epithelial tissue covers body surfaces, lines hollow organs, body cavities, and ducts; and forms glands.
      2. Connective tissue protects and supports the body and its organs, binds organs together, stores energy reserves as fat, and provides immunity.
      3. Muscle tissue is responsible for movement and generation of force.
      4. Nervous tissue initiates and transmits action potentials (nerve impulses) that help coordinate body activities.
      5. Clinical connection: biopsy

III. CELL JUNCTIONS
   A. Cell junctions are points of contact between adjacent plasma membranes.
   B. Depending on their structure, cell junctions may serve one of three functions.
      1. Some cell junctions form fluid-tight seals between cells.
      2. Other cell junctions anchor cells together or to extracellular material.
      3. Still others act as channels, which allow ions and molecules to pass from cell to cell within a tissue.
C. The five most important kinds of cell junctions are tight junctions, adherens junctions, desmosomes, hemidesmosomes, and gap junctions.
   1. Tight junctions form fluid-tight seals between cells and are common among epithelial cells that line the stomach, intestines, and urinary bladder (Figure 4.2a).
   2. Adherens junctions are made of plaque and anchor cells together (Figure 4.2b).

D. Transmembrane glycoproteins called cadherins join the cells
   1. Desmosomes are composed of plaque and are linked by transmembrane glycoproteins that extend across a gap between adjacent cell membranes and link the cytoskeletons of cells together (Figure 4.2c).
   2. Hemidesmosomes connect cells to extracellular material such as the basement membrane (Figure 4.2d).
   3. Gap junctions allow cells in a tissue to rapidly communicate through connexins, transmembrane protein channels that connect cells together (Figure 4.2e).

IV. COMPARISON BETWEEN EPITHELIAL AND CONNECTIVE TISSUES
   A. Major structural differences between an epithelial tissue and a connective tissue (Figure 4.3)
      1. The number of cells in relation to the extracellular matrix
         a. epithelial tissue many cells are tightly packed together with little or no extracellular matrix
         b. in a connective tissue a large amount of extracellular material separates cells
      2. Blood vessels
         a. epithelial tissue has no blood vessels
         b. most connective tissues have significant networks of blood vessels
      3. Epithelial tissues almost always form surface layers and are not covered by another tissue

V. EPITHELIAL TISSUES
   A. General Features of Epithelial Tissues
      1. Epithelial cells are arranged in sheets, in either single or multiple layers (Figure 4.4)
      2. Epithelium consists mostly of packer cells with little extracellular material.
      3. Many cell junctions are present, providing secure attachments among cells.
      4. An epithelial cell has an apical surface and a basal surface attached to a base membrane (Figure 4.4).
5. Epithelia adhere firmly to nearby connective tissue via a thin extracellular layer, the basement membrane (Figure 4.4).

6. Epithelial tissue is avascular; exchange of materials between epithelium and adjacent connective tissue is by diffusion.

7. Epithelia have a nerve supply.

8. Epithelia have a high capacity for renewal (a high mitotic rate).

9. Clinical connection: Basement membranes have a role in some diseases

B. Classification of Epithelial Tissue

1. Types of covering and lining epithelial tissue are classified according to the way the cells are arranged in layers and the shapes of the cells (Figure 4.5)

2. Layers are arranged as simple (one layer), stratified (several layers), and pseudostratified (one layer that appears as several).

3. Cell shapes include squamous (flat), cuboidal (cube-like), columnar (rectangular), and transitional (variable).

C. Covering and lining epithelia

1. may be classified as a combination of arrangement of layers and shape of the cells. The name of the specific type of stratified epithelium depends on the shape of the surface cells. Each of the epithelial tissues described in the following sections is illustrated in Table 4.1.

2. Clinical connection: Papanicolaou Test

D. Simple Epithelium

1. Simple squamous epithelium consists of a single layer of flat, scalelike cells (Table 4.1A)

   a. It is adapted for diffusion and filtration and is found in lungs and kidneys.
   b. It is found in parts of the body that are subject to little wear and tear.
   c. Endothelium lines the heart and blood vessels.
   d. Mesothelium lines the thoracic and abdominopelvic cavities and covers the organs within them.

2. Simple cuboidal epithelium consists of a simple layer of cube-shaped cells and performs the functions of secretion and absorption (Table 4.1B).

3. Simple columnar epithelium consists of a single layer of rectangular cells and can exist in two forms: nonciliated simple columnar epithelium and ciliated simple columnar epithelium.
a. Nonciliated simple columnar epithelium contains microvilli (Figure 3.2) to increase surface area and the rate of absorption and goblet cells that secrete mucus (Table 4.1C).

b. Ciliated simple columnar epithelium (Table 4.1D) contains cells with cilia, motile, hair-like processes that help to move fluids or particles along a surface.

4. *Pseudostratified epithelium* (Table 4.1E) has only one layer but gives the appearance of many.
   a. All cells are attached to the basement membrane but some do not reach the apical surface.
   b. In pseudostratified ciliated columnar epithelium, the cells that reach the surface either secrete mucus (goblet cells) or bear cilia that sweep away mucus and trapped foreign particles.
   c. Pseudostratified nonciliated columnar epithelium contains no cilia or goblet cells.

5. *Stratified squamous epithelium* consists of several layers of cells in which the top layer of cells is flat and the deeper layers of cells vary in shape from cuboidal to columnar (Table 4.1F).
   a. The basal cells replicate by mitosis and ultimately work their way to the surface.
   b. In keratinized stratified squamous epithelium, a tough layer of keratin (a protein resistant to friction and repels bacteria) is deposited in the surface cells.
   c. Nonkeratinized stratified squamous epithelium does not contain keratin and remains moist.
   d. A Papanicolaou smear or Pap Smear involves collecting samples of cells present in the secretions of the cervix and vagina for early detection of changes in the cells that might indicate cancer or a precancerous condition.

6. *Stratified cuboidal epithelium* (Table 4.1G) is a rare tissue consisting of two or more layers of cube-shaped cells whose function is mainly protective.

7. *Stratified columnar epithelium* (Table 4.1H) consists of several layers of cells of which only the top layer is columnar. It is somewhat rare and functions in protection and secretion.

8. *Transitional epithelium* (Table 4.1I) consists of several layers of cells whose appearance is variable.
   a. It is capable of stretching and thus permits distention of an organ.
   b. It lines the urinary bladder and portions of the ureters and the urethra.

E. Glandular Epithelium
1. General Features
   a. A gland is a single cell or a mass of epithelial cells adapted for secretion.
   b. *Endocrine glands* are ductless; their secretory products (hormones) enter the extracellular fluid and diffuse into the blood (Table 4.2a).
   c. *Exocrine glands* (sweat, oil, and digestive glands) secrete their products into ducts that empty at the surface of covering and lining epithelium or directly onto a free surface (Table 4.2b).

2. Structural Classification of Exocrine Glands
   a. *Unicellular glands* are single-celled, such as the goblet cell.
   b. *Multicellular glands* are composed of cells that form a distinctive microscopic structure or macroscopic organ, such as sweat, oil, and salivary glands.
      1) They occur in several different forms (Figure 4.6) including tubular glands, acinar glands, tubuloacinar glands, simple glands, and compound glands.
      2) Combining the shapes of the secretory portion with the degree of branching of the duct gives the structural classification for multicellular glands.

3. Functional classification of exocrine glands
   a. *Meroocrine glands* form the secretory products and discharge it by exocytosis (Figure 4.7a).
   b. *Apocrine glands* accumulate their secretary product at the apical surface of the secreting cell; that portion then pinches off from the rest of the cell to form the secretion with the remaining part of the cell repairing itself and repeating the process (Figure 4.7b).
   c. *Holocrine glands* accumulate the secretory product in the cytosol; when the cell dies, it and its products are discharged as the glandular secretion, with the discharged cell being replaced by a new one (Fig 4.7c).

VI. CONNECTIVE TISSUE
   A. General Features of Connective Tissue
      1. Connective tissue is the most abundant and widely distributed tissue in the body.
      2. Connective tissue consists of two basic elements: cells and extracellular matrix (formed from ground substance and fibers). Matrix is abundant with relatively few cells and tends to prevent tissue cells from touching one another.
3. The matrix of a connective tissue, which may be fluid, semifluid, gelatinous, fibrous, or calcified, is usually secreted by the connective tissue cells and adjacent cells and determines the tissue’s qualities.

4. Unlike epithelia, connective tissues do not occur on free surfaces.

5. Unlike epithelium, connective tissue is highly vascular (except for cartilage and tendons).

6. Except for cartilage, connective tissue, like epithelium, has a nerve supply.

B. Connective Tissue Cells

1. Cells in connective tissue are derived from mesenchyme.

2. Immature cells have names that end in -blast (e.g., fibroblast, chondroblast) while mature cells have names that end in -cyte (e.g., osteocyte).

3. Most mature cells have reduced capacity for cell division and matrix formation and are mostly involved in maintaining the matrix.
   a. fibroblasts (which secrete fibers and matrix). (Figure 4.8)
   b. macrophages (or histiocytes, which develop from monocytes and are phagocytic). (Figure 4.8)
   c. plasma cells (which develop into antibody-producing B lymphocytes, or B cells). (Figure 4.8)
   d. mast cells (which are abundant alongside blood vessels and produce histamine). (Figure 4.8)
   e. adipocytes (or fat cells, which store energy in the form of fat). (Figure 4.8)
   f. Leukocytes (white blood cells). (Figure 4.8)

C. Connective Tissue Extracellular Matrix

1. The ground substance, and fibers, deposited in the space between the cells comprises the matrix of connective tissue.

2. Substances found in the ground substance include hyaluronic acid, chondroitin sulfate, dermatan sulfate, and keratan sulfate. Collectively called glycosaminoglycans.

3. The function of ground substance is that it supports, binds, and provides a medium for the exchange of materials between the blood and cells, and is active in influencing cell functions.

4. **Clinical Connection**: Chondroitin sulfate, glucosamine and joint disease.

VII. Fibers

A. Fibers in the matrix provide strength and support for tissues.
B. Three types of fibers are embedded in the matrix between cells of connective tissues (Figure 4.8).

1. **Collagen fibers**, composed of the protein collagen, are very tough and resistant to stretching, yet allow some flexibility in tissue; they are found in bone, cartilage, tendons, and ligaments.

2. **Elastic fibers**, composed of the protein elastin, provide strength and stretching capacity and are found in skin, blood vessels, and lungs.

3. **Reticular fibers**, consisting of collagen and glycoprotein, provide support in the walls of blood vessels and form a strong, supporting network around fat cells, nerve fibers, and skeletal and smooth muscle fibers.

**VIII. Classification of Connective Tissue**

**A. Embryonic Connective Tissue**

1. Connective tissue that is present primarily in the embryo or fetus is called embryonic connective tissue.

**B. Mesenchyme**, found almost exclusively in the embryo, is the tissue form from which all other connective tissue eventually arises. (Table 4.3A)

**C. Mucous connective tissue** (Wharton’s jelly) is found in the umbilical cord of the fetus. (Table 4.3B)

**IX. Types of Mature Connective Tissue**

**A. Mature connective tissue** exists in the newborn, has cells differentiated from mesenchyme, and does not change after birth. It is subdivided into several kinds: connective tissue proper, cartilage, bone tissue, and blood. Subtypes include loose connective tissue, dense connective tissue, cartilage, bone, and blood.

**B. Loose connective tissue** consists of all three types of fibers, several types of cells, and a semifluid ground substance.

**C. Areolar connective tissue** is a prime example of loose connective tissue. It shows all of the typical loose connective tissue features. (Table 4.4A)

1. The ground substance aids the passage of nutrients from the blood vessels of the connective tissue into adjacent cells and tissues.

2. It is found in the subcutaneous layer.

**D. Adipose tissue** consists of adipocytes which are specialized for storage of triglycerides. (Table 4.4B)

1. It is found wherever areolar connective tissue is located.
2. It reduces heat loss through the skin, serves as an energy reserve, supports, protects, and generates considerable heat to help maintain proper body temperature in newborns (brown fat).

3. Clinical Connection: Liposuction may result in medical problems.

E. Reticular connective tissue consists of fine interlacing reticular fibers and reticular cells (Table 4.4C).
   1. It forms the stroma of certain organs.
   2. It helps to bind together the cells of smooth muscle.

F. Dense connective tissue contains more numerous, thicker, and dense fibers but considerably fewer cells than loose connective tissue.
   1. Dense regular connective tissue consists of bundles of collagen fibers in a regular and orderly, parallel arrangement that confers great strength (Table 4.4D).
   2. Dense irregular connective tissue contains collagen fibers that are irregularly arranged and is found in parts of the body where tensions are exerted in various directions (Table 4.4E).
      a. It usually occurs in sheets, such as the dermis of the skin.
      b. It is also found in heart valves, the perichondrium, the tissue surrounding cartilage, and the periosteum.

G. Elastic connective tissue consists of elastic fibers and fibroblasts (Table 4.4F).
   1. It is quite strong and can recoil back to its original shape after being stretched.
   2. It is found in lung tissue and elastic arteries.

H. Cartilage consists of a dense network of collagen fibers and elastic fibers embedded in chondroitin sulfate.
   1. Its strength is due to its collagen fibers; its resilience, to the chondroitin sulfate.
   2. Chondrocytes occur with spaces called lacunae in the matrix.
   3. It is surrounded by a dense irregular connective tissue membrane called the perichondrium.
   4. Unlike other connective tissues, cartilage has no blood vessels or nerves (except in the perichondrium).
   5. There are three major types of cartilage.
      a. Hyaline cartilage is the most abundant but weakest type of cartilage and has fine collagen fibers embedded in a gel-type matrix. It affords flexibility and support and, at joints, reduces friction and absorbs shock. (Table 4.6A)
b. *Fibrocartilage* contains bundles of collagen fibers in its matrix. It does not have a perichondrium. Combining strength and rigidity, it is the strongest of the three types of cartilage. (Table 4.6B)

c. *Elastic cartilage* contains a threadlike network of elastic fibers within the matrix. A perichondrium is present. It provides strength and elasticity and maintains the shape of certain organs. (Table 4.6C)

1) The growth of cartilage is accomplished by interstitial (endogenous) growth (expansion from within) and appositional (exogenous) growth (from without).

I. *Bone* (osseous tissue) consists of a matrix containing mineral salts and collagenous fibers and cells called osteocytes.

1. Bone is classified as either compact or spongy, depending on how the matrix and cells are organized.

2. The basic unit of compact bone is the osteon or Haversian system, consisting of four parts (Table 4.7).

3. The lamella are concentric rings of matrix that consist of mineral salts that give bone its hardness and collagen fibers that give bone its strength.

4. Lacunae are small spaces between lamellae that contain mature bone cells called osteocytes.

5. Canaliculi are minute canals containing processes of osteocytes that provide routes for nutrient and waste transport.

6. A central (Haversian) canal contains blood vessels and nerves.

7. *Spongy bone* has trabeculae rather than osteons.

8. Bone supports, protects, helps provide movement, stores minerals, and houses blood-forming tissue.

J. Liquid connective tissue

1. Blood (vascular tissue) consists of a liquid matrix called plasma and formed elements. (Table 4.8)

   a. Formed elements include erythrocytes, leukocytes, and thrombocytes.

      1) Red blood cells (erythrocytes) function in transporting respiratory gases.

      2) White blood cells (leukocytes) are involved in phagocytosis, immunity, and allergic reactions.

      3) Platelets (thrombocytes) function in blood clotting.

2. Lymph is interstitial fluid flowing in lymph vessels.
2. **Clinical Connection**: Tissue engineering has allowed scientists to grow new tissues in the laboratory for the replacement of damaged tissues.

X. **MEMBRANES**

A. **General Characteristics**
   1. Membranes are flat sheets of pliable tissue that cover or line a part of the body.
   2. Epithelial membranes consist of an epithelial layer and an underlying connective tissue layer and include mucous membranes, serous membranes, and the cutaneous membrane or skin.
   3. Synovial membranes line joints and contain only connective tissue.

B. **Epithelial Membranes**
   1. *Mucous membranes* (mucosae) line cavities that open to the exterior, such as the gastrointestinal tract(Figure 4.9a)
      a. The epithelial layer of a mucous membrane is an important aspect of the body’s defense mechanisms, acting as a barrier to pathogens and a trapping surface for particles.
      b. The connective tissue layer of a mucous membrane is called the lamina propria.
   2. *serous membrane*, or serosa, lines a body cavity that does not open directly to the exterior and covers the organs that lie within the cavity. Examples include the pleura, pericardium, and peritoneum (Figure 4.9b)
      a. These membranes consist of parietal and visceral portions.
      b. The epithelial layer secretes a lubricating serous fluid that reduces friction between organs and the walls of the cavities in which they are located.
   3. *cutaneous membrane*, or skin, covers the outside of the body (Figure 4.9c)
      a. The skin has two layers, the superficial epidermis, and the deeper dermis
      b. The epidermis consists of keratinized stratified squamous epithelium and the dermis consists of areolar and dense irregular connective tissues
   4. *Synovial membranes* line joint cavities, bursae, and tendon sheaths and do not contain epithelium; they also secrete a lubricating synovial fluid.(Figure 4.9 d)

XI. **MUSCULAR TISSUE**

A. **General Characteristics**
   1. Muscle tissue consists of fibers (cells) that are modified for contraction and thus provide motion, maintenance of posture, and heat production.
2. It is subdivided into three types.

B. **Skeletal muscle tissue**
   1. attached to bones, is striated, and is voluntary (Table 4.9A).

C. **Cardiac muscle tissue**
   1. forms most of the heart wall, is striated, and is usually involuntary (Table 4.9B).

D. **Smooth (visceral) muscle tissue**
   1. found in the walls of hollow internal structures (blood vessels and viscera), is nonstriated, and is usually involuntary. It provides motion (e.g., constriction of blood vessels and airways, propulsion of foods through the gastrointestinal tract, and contraction of the urinary bladder and gallbadder) (Table 4.9c).

XII. **NERVOUS TISSUE**

   A. **General Characteristics**
      1. The nervous system is composed of only two principal kinds of cells: neurons (nerve cells), and neuroglia (protective and supporting cells) (Table 4.10).
      2. Most neurons consist of a cell body and two types of processes called dendrites and axons.
      3. Neurons are sensitive to stimuli, convert stimuli into nerve impulses, and conduct nerve impulses to other neurons, muscle fibers, or glands.
      4. Neuroglia protect and support neurons and are often the sites of tumors of the nervous system.

XIII. **EXCITABLE CELLS**

   A. Excitable cells are so named because they can carry electrical signals,
   B. Neurons and muscle cells respond to neurotransmitters which cause the cells to generate the signals.

XIV. **TISSUE REPAIR: RESTORING HOMEOSTASIS**

   A. Tissue repair is the process that replaces worn out, damaged, or dead cells. Each of the four classes of tissues has a different capacity to replenish its parenchymal cells.
      1. Epithelial cells are replaced by the division of stem cells or by division of undifferentiated cells.
      2. Some connective tissues such as bone has a continuous capacity for renewal whereas cartilage replenishes cells less readily.
3. Muscle cells have a poor capacity for renewal.
4. Nervous tissue has a poor capacity for renewal
5. Fibrosis is the process of scar formation.
6. If the injury is extensive granulation tissue (actively growing connective tissue) is formed.
7. **Clinical Connection:** Adhesions, which sometimes result from scar tissue formation, cause abnormal joining of adjacent tissues, particularly in the abdomen and sites of previous surgery. These can cause problems such as intestinal obstruction.
8. Nutrition is important to tissue repair. Various vitamins (A, some B, D, C, E, and K) and a protein-rich diet are needed.
9. Proper blood circulation is essential in tissue repair.

**XV. AGING AND TISSUES**

A. The tissues of young people repair rapidly and efficiently; the process slows down with aging.
B. The younger body is generally in a better nutritional state, its tissues have a better blood supply, and its cells have a faster metabolic rate.

**XVI. DISORDERS: HOMEOSTATIC IMBALANCES**

A. Disorders of epithelial tissues are mainly specific to individual organs, such as skin cancer which involves the epidermis or peptic ulcer disease which involves the epithelial lining of the stomach or small intestine.

1. The most prevalent disorders of connective tissue are autoimmune disorders which are diseases in which antibodies produced by the immune system fail to distinguish what is foreign from what is self and attacks the body’s own tissues.
   a. Systemic lupus erythematosus is a chronic inflammatory disease of connective tissue.
